

UPWARD DEPLOYING INFLATABLE KNEE BOLSTER WITH MECHANICAL GUIDES

Field of the Invention

[0001] This invention relates to a knee bolster for a vehicle.

Background of the Invention

[0002] In a vehicle crash, the knee of a vehicle occupant is frequently susceptible to injury. A significant number of knee injuries results from impact forces on the leg that cause the lower leg (tibia) to travel in an opposite direction to the path of the upper leg (femur). As a consequence of this motion, the tibia shears relative to the femur, causing ligaments and tendons in the knee to tear.

[0003] Existing knee bolsters fail to address this shearing effect. For example, one such design merely deploys an air bag in the vicinity of the knee of the occupant. However, such an air bag does not prevent movement of the knee relative to the tibia because the air bag contacts both the knee and the tibia in deployment.

[0004] An alternative knee bolster design uses a mechanical carriage to direct a padded cushion toward the knee of the vehicle occupant. This design advances the padded cushion through a telescoping support. The telescoping support expands through either a spring or a pyrotechnic force within the telescoping support. This alternative design does not offer the benefits of cushioning a vehicle impact with an air bag.

[0005] A need therefore exists for a knee bolster that uses an air bag to stop movement of the femur relative to the tibia.

Summary of the Invention

[0006] The present invention uses an air bag to advance a knee bolster toward an anticipated location of a knee of a vehicle occupant. The air bag has a deflated condition and an inflated condition. The air bag is inflated by an air bag inflator. In contrast to existing designs, the inventive knee bolster uses a guide structure attached to the bolster to direct the bolster along a generally linear path toward the knee. In this way, the bolster may focus its cushioning effect on the knee rather than on both the knee and the tibia while still providing the cushioning effect from an air bag.

[0007] The guide structure may comprise a first member and a second member. The first member may extend from an unactuated position, when the air bag is deflated, to an actuated position, when the air bag is inflated, along a linear path relative to the second member. The first member may, in fact, be disposed within the second member and comprise a guide pin disposed within a guide tube. The guide pin may have a tapered surface to be received by another tapered surface of the guide tube.

[0008] The knee bolster may have an air bag housing to store the air bag in the deflated condition. The air bag may have a rear and a front area. The rear area is located closer to the air bag housing than the front area when the air bag is inflated. The knee bolster may be located at the front area of the air bag. A tether may attach the air bag to the knee bolster. Moreover, the knee bolster may be cushioned.

[0009] The guide structure may expand and retract between the actuated position and the unactuated position so that the air bag may be allowed to deflate once the vehicle occupant has contacted the knee bolster. Moreover, by placing the knee bolster at the front area of the air bag, the knee bolster may advance quickly and directly to the anticipated location of the knee. The vehicle occupant will also have the benefit of the full cushioning effect of the

air bag at this location. In this way, the knee bolster may move with the knee of the vehicle occupant to collapse the air bag from front to rear for a full cushioning.

[0010] The air bag is thus inflated. Because the knee bolster is attached to the air bag, the knee bolster advances with the air bag. The knee bolster may be directed along a linear path to the anticipated location of a knee.

Brief Description of the Drawings

[0011] The various features and advantages of this invention will become apparent to those skilled in the art from the following detailed description of the currently preferred embodiment. The drawings that accompany the detailed description can be briefly described as follows:

[0012] Figure 1 illustrates a side view of the inventive knee bolster with an air bag in an inflated condition.

[0013] Figure 2 illustrates a side view of the knee bolster with the air bag in a deflated condition.

[0014] Figure 3 illustrates an exploded view of the knee bolster of Figures 1 and 2.

[0015] Figure 4 illustrates the guide pin disposed within the guide tube in an unactuated position.

[0016] Figure 5 illustrates the guide pin extended from the guide tube in an actuated position.

Detailed Description of the Invention

[0017] Figure 1 illustrates a side view of inventive knee bolster 14. Inventive knee bolster 14 is located within vehicle 10, preferably under a vehicle instrument panel as shown. In Figure 1, knee bolster 14 is shown with air bag 18 in inflated condition 30 while, in Figure 2, air bag 18 is shown in deflated condition 34.

[0018] Inventive knee bolster 14 comprises air bag 18, air bag inflator 38, knee contact plate 42, and guide structure 54. In contrast to existing knee bolster designs, inventive knee bolster 14 uses guide structure 54 to direct knee contact plate 42 along linear path A to an anticipated location of a knee of a vehicle occupant 58.

[0019] The operation of inventive knee bolster 14 will now be explained. Figure 2 illustrates knee bolster 14 with air bag 18 in deflated condition 34 and knee contact plate 42 in unactuated position 50. As shown, air bag 18 has rear area 22 and front area 26. The contact plate 42 is located at front area 26 of air bag 18 while air bag housing 82 is located near rear area 22 of air bag 18. Air bag 18 is further in communication with air bag inflator 38. In the event of a vehicle crash, crash detection system 40 may instruct air bag inflator 38 to inflate air bag 18. Air bag 18 is attached to knee contact plate 42 through tethers 86, which wrap around air bag 18 and knee contact plate 42. Knee contact plate 42 may be cushioned. When air bag 18 expands from deflated condition 34 (see Figure 2) to inflated condition 30 (see Figure 1), knee contact plate 42 moves from unactuated position 50 along linear path A to actuated position 46, an anticipated location of a knee of the vehicle occupant. When the knee of the vehicle occupant contacts knee contact plate 42, air bag 18 as well as knee contact plate 42 collapses in the direction of arrow B to thereby cushion any vehicle impact.

[0020] Figure 3 illustrates an exploded view of inventive knee bolster 14. As shown in Figure 3, knee contact plate 42 is located at front area 26 of air bag 18. Rear area 22 of air bag 18 is located near air bag housing 82. Also, as shown, guide structure 54 comprises first member 66, here a guide pin, and second member 70, here a guide tube.

[0021] As shown in Figures 4 and 5, first member 66 is disposed within second member 70. In addition, first member 66 has first tapered surface 74 while second member 70 has tapered surface 78. In Figure 4, with first member 66 at unactuated position 50, first tapered surface 74 is spaced away from second tapered surface 78. However, in Figure 5, when guide structure 54 is in actuated position 46, first tapered surface 74 is in contact with second tapered surface 78 to smoothly retain first member 66 within second member 70. In this way, the force of actuation by air bag 18 may be distributed across tapered surfaces 74 and 78 rather than abruptly stopped.

[0022] The aforementioned description is exemplary rather than limiting. Many modifications and variations of the present invention are possible in light of the above teachings. The preferred embodiments of this invention have been disclosed. However, one of ordinary skill in the art would recognize that certain modifications would come within the scope of this invention. Hence, within the scope of the appended claims, the invention may be practiced otherwise than as specifically described. For this reason the following claims should be studied to determine the true scope and content of this invention.
